

SPECIFICATION

TITLE OF THE INVENTION

“COMPOSITIONS AND METHODS AGAINST INFLAMMATORY PROCESSES”

5

CROSS REFERENCE TO RELATED APPLICATIONS

This application claims the benefit of U.S. Provisional Application No. 60/391,739 filed June 26, 2002, the disclosure of which is herein incorporated by reference.

10

BACKGROUND OF THE INVENTION

The present invention generally relates to compositions. More specifically, the present invention relates to compositions that include thermally processed (e.g., extruded) plant material, such as chicory and/or extracts thereof, to enhance health in humans and animals. The plant material is derived from, for example, the *Asteraceae* plant family that contain desirable and effective quantities of sesquiterpene lactones, thus yielding an active fragment thereof, such as α -methylene- γ -butyrolactone (α -MGBL) upon heating or other plants that contain the same or substantially the same class of compounds, such as coffee or soja.

The need to enhance health in mammals has involved and continues to involve on-going research efforts and discoveries to prevent and/or treat disease. For example, irritation or discomfort can result from inflammation in a mammal due to, for example, skin inflammation, eye inflammation, gut inflammation or the like. Further, it is generally believed that chronic inflammation may increase the risk to develop other disease or ailment, such as osteoarthritis, autoimmune disease, cancer or the like. In this regard, it is generally understood that inflammation is triggered by an enhanced transcription activity of transcription factor NF- κ B that leads to the expression of proinflammatory and inflammatory enzymes and receptors. More specifically, inflammation can occur due to increased enzyme activity in the mammal, such as an increased activity of cyclooxygenase including cyclooxygenase-1, cyclooxygenase-2 or the like.

In general, food, dietary or other nutritional sources are known to contain a number of constituents or agents that are believed to be capable of protecting against disease in humans and animals. For example, oligosaccharides, such as inulin and various fructo-oligosaccharides, are reported to have prebiotic effects, such as
5 promoting the growth of bifido- and lacto-bacteria in the gastro-intestinal tract at the expense of pathogens including, for example, *Clostridium perfringens*. See, for example, Gibson et al., Food Microbiology, 11 (6), pp. 491-498 (1994). Although most reported experimentation has been carried out in vitro, there have been reports that these oligosacchrides have a similar effect in the gut of rats and humans. In this
10 regard, it is generally known that the promotion of growth of bifido- and lacto-bacteria through the use of oligosacchrides can provide a variety of different beneficial effects on animals and humans, such as the prevention and/or treatment of diarrhea, increased growth, improved ability to breed or other like beneficial effects which enhance health.

Inulin or other dietary agents that are believed to promote health in humans and
15 animals as discussed above, in general, can be derived from plants or other natural sources. For example, inulin is generally known to be purified from plants that contain high concentrations of inulin, such as chicory, Jerusalem artichoke, leek and asparagus. In this regard, the plant is typically purified or otherwise treated prior to use in order to enhance a plant's flavor, such as to eliminate, or at least minimize, a bitter
20 flavor typically associated with chicory. See, for example, U.S. 4,865,852.

In general, the purified plant product is prepared by hydrolyzation with acids or enzymes. The hydrolysate is then collected and condensed to obtain the bioactive agent, such as inulin. For example, JP 63-309147 discloses grinding chicory tubers, partially hydrolyzing them with acids, and then drying the hydrolysate with or without
25 neutralization. However, the purification of, for example, fructo-oligosaccharides and inulin, can greatly add to the cost of the dietary product. Consequently, the use of such dietary products has been generally limited to specialty food or dietary products in humans and animals.

A need, therefore, exists for a composition that includes natural ingredients,
30 such as thermally processed chicory and/or extracts thereof, that are palatable to humans and animals, that can be inexpensively produced, and that can enhance health in humans and animals, such as the prevention and/or treatment of inflammation.

SUMMARY OF THE INVENTION

The present invention relates to compositions that can be utilized to enhance health in humans and animals, particularly the prevention and/or treatment of inflammation. The compositions of the present invention include one or more
5 phytochemical agents derived from a thermally processed (e.g., extruded) plant source, such as chicory.

Applicants have demonstrated that chicory root extracts contain one or more phytochemicals with the ability to inhibit enzyme and/or transcription activity in mammals, such as enzyme activity relating to cyclooxygenase and transcription
10 activity relating to NF- κ B. Applicants further demonstrated that thermally processed (e.g., extruded) chicory root extracts possess an enhanced enzyme inhibition activity relating to cyclooxygenase and/or enhanced inhibition related to NF- κ B. Applicants demonstrated a relationship between the enhancement of inhibition to the generation during thermal processing of an active molecular species, namely α -methylene- γ -
15 butyrolactone (α -MGBL).

In this regard, the inhibition of such enzyme/transcription activity was proven to prevent and/or treat inflammation in mammals. By inhibiting the inflammatory process, the risk of incidence of other disease or ailments, such as cancer, which are believed to result from inflammation (e.g., chronic inflammation) may be reduced.

20 To this end, in an embodiment of the present invention, a nutritional composition is provided. The composition includes a therapeutically effective amount of a plant material that includes one or more thermally processed (e.g., extruded) phytochemical agents capable of inhibiting enzymatic activity to prevent and/or treat inflammation in a mammal. Preferably, the plant material comprises an amount of at
25 least 0.5% by weight.

The plant material, in an embodiment, is derived from the Asteraceae plant family or some other plants, such as coffee, soja, the like or combinations thereof. Preferably, the plant material is derived from chicory, lettuce, coffee, soja, the like or combinations thereof. In an embodiment, the plant material includes a chicory extract.

30 The compositions can include other dietary agents derived from the plant source in addition to the phytochemical agents. These dietary agents can include any suitable constituent capable of inhibiting enzymatic activity associated with

cyclooxygenase. In an embodiment, the dietary agents in addition to phytochemicals include antioxidants, glucosamine, chondroitin sulphate, omega-3 fatty acids, any suitable other dietary agents and combinations thereof.

5 The present invention also provides a pet food product. The pet food product includes a starch matrix; and an effective amount of a thermally processed (e.g., extruded) plant material that includes a phytochemical agent capable of inhibiting enzyme activity in a mammal to reduce a risk of inflammation.

10 In another embodiment of the present invention, a process for preparing a nutritional food product capable of reducing a risk of incidence of inflammation in a mammal is provided. The process includes the steps of providing a plant material; thermal processing of the plant material to form a plant extract including one or more phytochemical agents capable of inhibiting enzyme activity in the mammal; and processing the plant extract and one or more food ingredients to form the nutritional food product that includes at least 1% by weight of the plant extract.

15 Preferably, the plant extract is processed by defatting the plant material to form a first plant extract and subsequently processing the first plant extract with ethyl acetate via acid hydrolysis to form the plant extract.

20 The present invention also provides the use of a therapeutically effective amount of a thermally processed, such as extruded, plant material including one or more phytochemical agents capable of inhibiting enzyme activity in the mammal, for the preparation of a composition intended for reducing a risk of inflammation in a mammal at risk of inflammation. With decreased enzyme activity, the risk of inflammation in the mammal can be reduced thereby reducing a risk of other ailments or disease that may result from the inflammation, such as osteoarthritis, autoimmune disease, cancer or the like.

25 An advantage of the present invention is to provide an improved composition that can be utilized to reduce a risk of incidence of inflammation in mammals. In this regard, the composition is capable of inhibiting enzyme activity, the result of which is believed to treat and/or prevent inflammation.

30 Another advantage of the present invention is to provide an improved composition that includes a plant material containing one or more phytochemicals

capable of inhibiting an enzymatic activity, such as relating to cyclooxygenase, which is believed to prevent and/or treat inflammation in mammals.

Yet another advantage of the present invention is to provide methods of producing improved compositions containing a plant material that can enhance the palatability of the composition while maintaining the enzymatic inhibition properties of the plant material which are capable of reducing a risk of inflammation in mammals.

Yet still another advantage of the present invention is to provide methods of treatment and/or prevention against inflammation in mammals that include the administration of an improved composition.

Additional features and advantages of the present invention are described in, and will be apparent from, the following Detailed Description of the Invention and the figures.

BRIEF DESCRIPTION OF THE FIGURES

Figure 1 illustrates the inhibition of COX-2 expression in HT29 cells by α -methylene- γ -butyrolactone (α -MGBL) pursuant to an embodiment of the present invention.

DETAILED DESCRIPTION OF THE INVENTION

The present invention relates to compositions that at least include one or more phytochemical agents derived from thermally processed, such as extruded, natural sources, such as a plant material that can be utilized to effectively prevent and/or treat inflammation in humans and animals.

Applicants have surprisingly discovered that upon thermal processing certain plants and/or plant extracts thereof, such as chicory, phytochemicals and the like, can be generated with enhanced inhibition of cyclooxygenase enzyme activity and/or enhanced transcription activity of NF- κ B in mammals which is believed to reduce the risk of inflammation including, for example, skin inflammation, eye inflammation, gut inflammation, colon inflammation and the like. In an embodiment, the enzymatic activity is derived from cyclooxygenase, such as cyclooxygenase-1 and/or cyclooxygenase-2.

Applicants have demonstrated through testing that thermally processed, such as extruded, plant extracts, particularly chicory extracts, can inhibit cyclooxygenase activity as well as transcription activity of NF- κ B. In particular, it is believed that the thermally processed (e.g., extruded) chicory extracts have a more pronounced effect on the inhibition of cyclooxygenase-2 as compared to cyclooxygenase-1. Thus, the inhibition of this type of enzyme activity is believed to reduce inflammation in mammals. By reducing inflammation, it is believed that the risk of incidence of other disease or ailments which are believed to result from inflammation, particularly chronic levels of inflammation, may be reduced. The other types of disease can include, for example, cancer, autoimmune disease, osteoarthritis, and combinations thereof.

In addition to phytochemicals as discussed above, plants, such as chicory, are known to also contain prebiotic fibers, such as oligosacchrides including inulin, that are believed to reduce cancer incidence, particularly in the colon. In this regard, Applicants believe that enhanced benefits with respect to cancer prevention and/or treatment in humans and animals can be realized due to the combined effect of prebiotic fibers and phytochemicals that can inhibit enzyme activity to prevent and/or treat inflammation in mammals, particularly chronic inflammation which may cause cancer, such as colon cancer, if the inflammation is untreated.

Applicants have also demonstrated that the enzyme inhibiting properties of the thermally processed (e.g., extruded) composition of the present invention are essentially unaffected by the processing conditions under which the compositions are prepared pursuant to present invention. For example, purification of the plant material made pursuant to the present invention which can be utilized to reduce the bitterness of the plant extract and thus enhance human and animal palatability has negligible, if any, effect on the nutritional properties of the resultant purified product. In this regard, resultant extract product can result from essentially crude plant extracts, such as chicory. This can eliminate the need for expensive purification or other like treatment of the plant material necessary to produce the resultant bioactive fractions.

As used herein, the term "bioactive agent" or other like terms, such as "bioactive fractions", means any constituent or constituents that can display biological activity, chemical activity or like activity in a mammal(s) that are capable of

enhancing health in a mammal. Examples of bioactive agents include, for example, prebiotic fibers, phytochemicals or the like.

As used herein, the term "prebiotic" or other like terms including "prebiotic fiber" means a substance or a constituent that can promote the growth of microorganisms in mammals.

As used herein, the term "phytochemical" or other like terms including "phytochemicals" and "phytochemical agent" means any chemical produced by a plant that is believed to impart health benefits to humans and/or animals, such as the prevention and/or treatment of inflammation or other like disease.

As used herein, the term "enzyme activity" or other like terms, such as "enzymatic activity" means any suitable enzyme which can act as a catalyst during any suitable biological, chemical or other like process which is believed to effect the health in a mammal. For example, the inhibition of enzyme activity relating to cyclooxygenase is believed to reduce the risk of incidence of inflammation.

As used herein, the term "thermal processing" or other like terms, such as "extrusion", "extruding" and "extruded" means heating of the plant raw material and/or plant extract above standard temperature (e.g., 25° Celsius or 278 Kelvins) in a dedicated device, such as oven or extruder, or any similar device capable of increasing the temperature of the treated material.

The composition can include any suitable and compatible types and amounts of constituents such that the composition can be effectively utilized to prevent and/or treat inflammation. In an embodiment, the composition includes a plant material that contains one or more prebiotic fibers and phytochemical agents which is capable of inhibiting enzyme activity, such as enzyme activity relating to cyclooxygenase. This is believed to be responsible for the treatment and/or prevention of inflammation. A number of plant materials can be effectively added to the composition including, for example, chicory, lettuce, coffee, soja, Jerusalem artichoke, leek, asparagus, extracts thereof and combinations thereof. In an embodiment, chicory and/or chicory extract are preferred.

It should be appreciated that the plant material can be processed to form an extract in a variety of different and suitable ways. In general, the plant material, such as the chicory root, is ground, powderized or provided in any suitable form. The plant

material can then be further processed in a number of different stages to produce the product extract. In an embodiment, a defatting procedure is performed on the plant material to produce an extract that results from fats removed from the plant material. The defatting procedure can be conducted under any suitable defatting process
5 conditions with any suitable types and amounts of solvents including, for example, hexane.

In an embodiment, the resultant extract of the defatting procedure can be further processed via acid hydrolysis to produce another type of plant extract that can be added to the composition of the present invention. The acid hydrolysis procedure
10 can be conducted under any suitable process condition with any suitable types and amounts of solvents, including, for example, ethyl acetate.

In an embodiment, the extract from the defatting procedure can be further processed via a solvent extraction procedure. The solvent extraction can be carried out under any suitable process conditions and in the presence of any suitable amount and
15 type of solvent. In an embodiment, the solvent includes a solution of methanol ("MeOH") and water mixed in a 1:1 volume ratio. The resultant solution of the solvent extraction procedure can be further processed by evaporation of the solvent under suitable conditions to produce another extract. Alternatively, the resultant solution can be treated with an adsorbant agent, such as polyvinylpolypyrrolidone or the like, to
20 trap polyphenols. The adsorbant agent treatment can be carried out under any suitable process conditions. Specific examples of preparing plant extracts in accordance with an embodiment of the present invention are detailed below.

In an embodiment, the ground plant raw material is processed thermally. Applicants have demonstrated that in this way the raw plant material that naturally
25 contains sesquiterpene lactones (SQLs) is enriched in a highly active COX2 inhibitory species, namely α -methylene- γ -butyrolactone (α -MGBL). Indeed, this molecule exhibits an enhanced thermal stability compared to other SQLs. For example, this molecular species was demonstrated to inhibit inflammatory activity in part through direct interaction with transcription factor NF- κ B and the inhibition of its binding to
30 DNA. The inhibition was proposed to result from the alkylation a precise amino acid Cys³⁸ in the p65 domain of NF- κ B. The inhibition results in the decrease of expression of several proinflammatory and inflammatory receptors and enzymes, among which

cyclooxygenase-II. SQLs, in general, and α -MGBL in particular inhibit COX-2 activity and/or its expression. Applicants have demonstrated that α -CH₂- γ -butyrolactone inhibits specifically and with high potency COX-2 activity.

In an embodiment, the prebiotic fiber(s) and phytochemical agent(s) of the composition can be derived from a common or the same plant material, such as chicory. As previously discussed, Applicants believe that the combined effect of the prebiotic fiber and phytochemical source of plants, such as chicory, can result in an enhanced chemoprotective effect such that inflammation in mammals can be treated and/or prevented. The prebiotic fiber can include any suitable amount and type including, for example, oligosacchrides, such as inulin and various fructo-oligosacchrides, soy oligosacchrides and combinations thereof.

The phytochemical agents can include any suitable type and amount such that it is capable of inhibiting COX-II enzyme activity or NF- κ B transcription activity that are believed to be responsible for the prevention and/or treatment of inflammation. In an embodiment, the phytochemical agent of the plant material is capable of inhibiting cyclooxygenase activity, such as cyclooxygenase-1 and/or cyclooxygenase-2 and/or NF- κ B transcription activity. By inhibiting enzyme and/or transcription activity, the phytochemicals of the present invention are believed to be capable of preventing and/or treating inflammation, including, for example, chronic inflammation. In this regard, the risk of incidence of other disease or ailments which are believed to be caused by inflammation, such as cancer, osteoarthritis, autoimmune disease, may be reduced.

In addition to the phytochemicals, the plant source can include other dietary agents which are capable of inhibiting enzyme activity. In an embodiment, the dietary agent include antioxidants, glucosamine, chondroitin sulphate, omega-3 fatty acids, the like and combinations thereof.

It should be appreciated that the composition of the present invention can include a variety of different and suitable forms. In an embodiment, the composition can include a nutritional supplement, a food preparation for humans and/or animals, pet food and/or pharmaceutical and/or functional food composition or the like. The composition can be added to the food product in any suitable amount. In an embodiment, the food product includes the plant material of the composition in an

amount of at least 0.5% by weight, preferably from about 1% to about 30% by weight, more preferably about 1% to about 2% by weight.

In another embodiment, the pharmaceutical compositions containing the active ingredient(s) (e.g. α -methylene- γ -butyrolactone, fragments or extracts containing it) may be in any form suitable for oral use, such as e.g. tablets, troches, lozenges, aqueous or oily suspensions, dispersible powders or granules, emulsions, hard or soft capsules, or syrups or elixirs. Compositions intended for oral use may be prepared according to any method known in the art for the manufacture of pharmaceutical compositions and such compositions may contain one or more agents selected from the group consisting of sweetening agents, flavoring agents, coloring agents and preserving agents in order to provide pharmaceutically elegant and palatable preparations. Tablets contain the active ingredient(s) in admixture with non-toxic pharmaceutically acceptable excipients, such as inert diluents, granulating, disintegrating and lubricating agents, which are suitable for the manufacture of tablets. The tablets may be uncoated or they may be coated by known techniques to delay disintegration and absorption in the gastrointestinal tract and thereby provide a sustained action over a longer period. Formulations for oral use may also be presented as hard gelatin capsules wherein the active ingredient is mixed with an inert solid diluent, or as soft gelatin capsules wherein the active ingredients is mixed with water or an oil medium. Aqueous suspensions contain the active material in admixture with excipients suitable for the manufacture of aqueous suspensions, such as e.g. suspending agents, dispersing or wetting agents, preservatives, coloring agents, flavoring agents, and sweetening agents. Dispersible powders and granules suitable for preparation of an aqueous suspension by the addition of water provide the active ingredient(s) in admixture with a dispersing or wetting agent, suspending agent and one or more preservatives. Additional excipients, for example sweetening, flavoring and coloring agents, may also be present.

In an embodiment, the present invention provides a pet food product that includes a starch matrix and an effective amount of a plant material wherein the plant material includes a prebiotic fiber and phytochemical agent capable of inhibiting enzymes or enzyme activity in order to enhance health in mammals, such as to prevent and/or treat inflammation. The pet food product of the present invention can include

any suitable number, type and amount of constituents and be processed in any suitable way to form a desirable product form.

In an embodiment, the present invention includes a gelatinized cereal product which contains an amount of a plant material. The plant material at least includes a source of prebiotic fibers and phytochemicals capable of inhibiting enzymatic activity in mammals which is believed to enhance health in the mammal.

In an embodiment, the plant includes inulin, sufficient to provide at least about 0.25% by weight inulin, on a dry matter basis. The plant material used may be any suitable source, for example, chicory, lettuce, coffee, soja, Jerusalem artichoke, leek, onion, yacon, asparagus, which contains high levels of inulin, and mixtures of these plants. In an embodiment, chicory, and Jerusalem artichoke are preferred. In an embodiment, the plant materials include at least 50% by weight of inulin. For ease of handling, the plant material is preferably in a dried and comminuted or powder form. As described below, the processes utilize dried, comminuted chicory and/or extracts thereof. However, it is to be understood that any suitable plant material may be used in any suitable form and added to the cereal product in any suitable amount.

As described below, the remaining ingredients included in the gelatinized cereal product may be any suitable ingredients commonly used in gelatinized cereal products. Usually these ingredients include a starch source and a protein source. Suitable starch sources are, for example, grains such as corn, rice, wheat, beets, barley, oats, soy, and mixtures thereof. Suitable protein sources may be selected from any suitable animal or vegetable protein source. Examples include meat meal, bone meal, fish meal, soy protein concentrates, milk proteins, gluten, and the like. The choice of the starch and protein sources will be largely determined by the nutritional needs of the animal or human, palatability considerations, the type of cereal product produced or other like considerations. Various other ingredients, for example, sugar, salt, spices, seasonings, vitamins, minerals, flavoring agents, fats and the like may also be incorporated into the gelatinized cereal product as desired.

The gelatinized cereal product may be produced in many different ways as desired. However, for a dried cereal product, an especially suitable way of producing the product is extrusion cooking. This may be done as is well known in the art. For

example, in one suitable process, a feed mixture is fed into a preconditioner. The feed mixture is primarily made up of a starch source, a protein source, and the plant material, such as, chicory. In an embodiment, the chicory includes at least about 1% by weight of the feed material, preferably at least about 2% by weight. In an embodiment, the amount of plant material in the food material ranges from about 10% to about 20% by weight, preferably about 10% by weight.

In the preconditioner, water or steam, or both, is mixed into the feed mixture. A sufficient amount of water or steam is mixed into the feed mixture to moisten the feed mixture. If desired, the temperature of the feed mixture may be raised in the preconditioner to about 60°C to about 90°C by weight. A suitable preconditioner is described in US 4,752,139. It should be appreciated that the use a preconditioner is not required.

The moistened feed leaving the preconditioner is then fed into an extruder. The extruder may be any suitable single or twin screw and cooking extruder. Suitable extruders may be obtained from Wenger Manufacturing Inc., Clextral SA, Bühler AG, and the like. During passage through the extruder, the moistened feed passes through a cooking zone, in which it is subjected to mechanical shear and is heated. In an embodiment, the moistened feed is heated up to a maximum temperature of up to about 150°C, and a forming zone. The gauge pressure in the forming zone is about 300 kPa to about 10 MPa as desired. If desired, water or steam, or both, may be introduced into the cooking zone. During passage through the extruder, the starch source of the moistened feed is gelatinized to provide a gelatinized matrix structure primarily of starch, protein and the plant material, such as chicory.

The gelatinized matrix leaving the extruder is forced through a suitable die for example, a die as described in EP 0665051. A shaped extrudate, which has a cross-sectional shape corresponding to that of the orifice of the die, leaves the die. Depending upon the conditions in the extruder and the starch source used, the shaped extrudate expands to a greater or lesser extent. The shaped extrudate is then cut into pieces using blades. The individual pieces are then dried and, if desired, coated with protective or flavoring agents, or both. After cooling, the pieces may be packed into suitable packages. Alternatively, the individual pieces may be formed into flakes and then dried.

Depending upon the ingredients used, the gelatinized cereal product may be in the form of dried kibbles suitable for use as pet foods, expanded pieces suitable for use in breakfast cereals, flakes suitable for use in breakfast cereals, and the like.

It is also possible to produce a dried cereal product by mixing together water and the ingredients of cereal product, for example, by mixing in a preconditioner. The wet mixture may then be shaped into a desired shape by using, for example, shaping rollers. The shaped mixture may then be baked in an oven, at any suitable temperature. In an embodiment, the temperature ranges from about 220°C to about 280°C for a suitable baking time. In an embodiment, the baking time ranges from about 10 minutes to about 1 hour. The dried cereal product has the appearance of a baked biscuit.

If it is desired to produce a simulated meat product which may be used in canned pet foods, any suitable process can be used. For example, the processes can include those described in U.S. 4,781,939 and 5,132,137. In these processes, a protein source, especially a meat material, is emulsified. The meat material may be any suitable source of animal protein including for example, the muscular or skeletal meat of mammals, poultry, and fish or meat by-products such as hearts, liver, kidneys, tongue and the like, or meat meals. Vegetable protein sources may also be included if desired. The exact composition may be selected according to cost and the desired flavor. The emulsification may be carried out in any suitable equipment.

The dried chicory is added to the emulsion. Also, if desired or needed, additional protein may be added to the emulsion. The additional protein may be any protein source as mentioned above. The exact choice will depend upon availability, cost and palatability. The additional protein can be added in any suitable amount. In an embodiment, the additional protein can be added in an amount ranging from about 5% to about 35% by weight.

If desired or required, fats may also be added to the emulsion. Usually the amount of fat in the emulsion must be controlled to facilitate processing and to obtain an acceptable product. However, the meat material may well contain the desired amount of fats and hence adjustment may not be necessary. Typically, at this stage the emulsion contains a maximum fat level of about 25% by weight. In an embodiment, the amount of fat in the emulsion is in the range of about 5% to 15% by weight, more preferably about 7% to about 12% by weight. The mass ratio of protein to fat in the

emulsion is preferably about 1:1 to about 7:1. If added, the fats may be any suitable animal fats, such as tallow, or may be vegetable fats.

Additional ingredients such as sugars, salts, spices, seasonings, flavoring agents, minerals, and the like may also be added to the emulsion. In an embodiment, 5 the amount of additional ingredients used ranges from about 1% to about 5% by weight of the gelatinized cereal product.

Water may also be added to provide from about 45% to 80% by weight moisture in the emulsion. If sufficient moisture is present in the meat material, water need not be added.

10 Once mixed, the emulsion is preferably fed through a vacuum stuffer, or similar de-aeration apparatus, to de-aerate the emulsion. This removes air which may otherwise cause disruption of the formulated emulsion product and reduce its meat-like appearance. The emulsion is then fed to an emulsion mill which subjects the emulsion to rapid mechanical heating and shearing. Any suitable emulsion mill may be used 15 including, for example, the emulsion mill disclosed in U.S. 5,132,137. Other suitable emulsion mills are commercially available under the trade name of TRIGONAL and may be obtained from Siefer Maschinenfabrik GmbH & Co KG, Bahnhofstrasse 114, Postfach 101008., Velbert 1, Germany.

The temperature of the emulsion can be raised to the desired coagulation 20 temperature in the emulsion mill in a few seconds. In an embodiment, the coagulation temperature ranges from about 100°C to about 120°C. In an embodiment, the temperature ranges from about 45°C to about 75°C as described in U.S. 5,132,137. In general, the mechanical energy generated in the emulsion mill will be sufficient to heat the emulsion to the desired temperature but this may be supplemented by the injection 25 of superheated steam.

The heated emulsion leaving the emulsion mill can be transferred to a holding tube. In the holding tube, the heated emulsion coagulates while moving slowly along the holding tube. The residence time of the heated emulsion in the holding tube is sufficient for the emulsion to have coagulated into a firm emulsion product upon 30 reaching the exit of the holding tube. The firm emulsion product leaving the holding tube is then transferred to a cutter where it is cut into pieces, such as chunks, of size suitable for use in a pet food. The chunks have the appearance and texture of meat.

The chunks may be subjected to flaking if desired. The chunks may also be formulated into a chunk-in-gravy type of product. Other procedures for producing chunks are known and may be used, such as extruding a feed mixture, cooking the feed mixture in a steam oven, and the cutting of the cooked extrudate into chunks.

5 If it is desired to produce a canned pet food in the form of a meat loaf, a meat batter may be prepared by emulsifying a suitable meat material to produce a meat emulsion. The meat material may be any suitable meat source, for example, as described above. Suitable gelling agents including gums, such as kappacarrageenan, locust bean gum, guar gum, xanthan gum or the like, may be added to the meat
10 emulsion. In an embodiment, no more than about 2% by weight of gum is used. The dried plant material, such as chicory is then added to the meat emulsion.

Additional ingredients such as sugars, salts, spices, seasonings, flavoring agents, minerals, and the like may also be added to the meat emulsion. The amount of additional ingredients used is preferably such that they make up about 0.25% to about
15 5% by weight of the meat batter. Water may also be added the meat emulsion to provide from about 70% to about 85% by weight. If sufficient moisture is present in the meat material, water need not be added.

The meat emulsion is then heated to a temperature above about 65°C in a mixer-cooker. Steam may be injected into the meat batter if desired. The heated meat
20 emulsion is then again emulsified to provide a loaf batter and the loaf batter maintained at a temperature above about 60°C until filling into cans.

It should be appreciated that the gelatinized cereal product may be produced by any suitable process and not only those described above. Other types of oligosaccharides may also be included in the gelatinized cereal product such as fructo
25 oligosaccharide and soy oligosaccharide. The soy oligosaccharides may be added in the form of soy meal or other suitable soy source.

The cereal products may be in any suitable form including; for example, dried, semi-wet and wet. However, the matrix that makes up the cereal product must be gelatinized in order to remove or destroy the sesquiterpene compounds that may be
30 present in the plant material. It should be appreciated that the cereal product of the present invention can be made for human and/or animal consumption.

By way of example, and not limitation, examples of pet food products made pursuant to an embodiment of the present invention are illustrated below.

EXAMPLE 1: Dried Pet Food

5 A feed mixture is made up of about 58% by weight of corn, about 6% by weight of corn gluten, about 23% by weight of meat and meal, dried chicory and salts, vitamins and minerals making up the remainder. The dried chicory is in the form of a chicory extract made pursuant to an embodiment of the present invention and added in an amount of about 5% or less. The feed mixture is fed into a preconditioner and
10 moistened. The moistened feed is then fed into an extruder-cooker and gelatinized. The gelatinized matrix as it leaves the extruder is forced through a die and extruded, thus forming an extrudate. The extrudate is cut into pieces suitable for feeding to dogs, dried at about 110°C for about 20 minutes, and cooled to form pellets. It should be appreciated that part or a totality of the fat mix, or of the fat and oils used, can be
15 added at a later stage, for example, as a coating.

 The added chicory can enhance the pet's health by, for example, preventing and/or treating inflammation as previously discussed.

EXAMPLE 2: Dried Pet Food

20 A dry pet food is prepared like the dried pet food of Example 1. It further includes an additional ingredient typically associated with enhancing the palatability of the dry pet food suited to cats. The added chicory can enhance the pet's health by, for example, preventing and/or treating inflammation as previously discussed.

25 EXAMPLE 3: Dry Cat Food

 A feed mixture is made up of about 58% by weight of corn, about 6% by weight of corn gluten, about 23% by weight of chicken meal, dried chicory and salts, vitamins and minerals making up the remainder. The chicory is added in an amount of about 5% or less. As previously discussed, the added chicory can inhibit enzymatic
30 activity which is believed to enhance health in the animal by, for example, treating and/or preventing inflammation.

The feed mixture is fed into a preconditioner and moistened. The moistened feed is then fed into an extruder-cooker and gelatinized. The gelatinized matrix as it leaves the extruder is forced through a die and extruded, thus forming an extrudate. The extrudate is cut into pieces suitable for feeding to cats, dried at about 110°C for about 20 minutes, and cooled to form pellets. At this stage, a lyophilized powder of one or more strains of the *Lactobacillus* species, such as *Lactobacillus rhamnosus* NCC2583 (CNCM I-2449), *Lactobacillus acidophilus* NCC2628 (CNCM I-2453) and *Enterococcus faecium* SF68 (NCIMB 10415), is applied to the pellets. A sufficient amount of the powder is applied to the pellets such that the corresponding dietary intake amount for the cat is from about 1.0E+07 to about 1.0E+9 cfu / day. In this regard, a portion of the powder is mixed into a first mass of pellets which are subsequently bagged. A second portion of the powder is measured and mixed with a lipid carrier which is then sprayed on to a second mass of pellets. The pellets are bagged after the coating has dried sufficiently at 50-60°C for some minutes.

15

EXAMPLE 4: Canned Pet Food and Supplement

A mixture is prepared from about 73% of poultry carcass, pig lungs and beef liver (ground), about 16% of wheat flour, about 2% of dyes, vitamins, and inorganic salts. This mixture is emulsified at 12°C and extruded into the form of a pudding. Dried chicory in the form of an extract made pursuant to an embodiment of the present invention is added to the emulsion in an amount of about 5% or less. The emulsion is then cooked at a temperature of 90°C. It is cooled to 30°C and then cut into chunks. About 45% of the chunks are mixed with about 55% of a sauce that is prepared from about 98% of water, about 1% of dye and about 1% of guar gum. Tinplate cans are filled with the chunk and sauce mixture and sterilized at 125°C for about 40 minutes.

As a probiotic supplement to be mixed with the pet food before serving, additional packaging in sachet form with strains of the following *Lactobacillus* species are provided *Lactobacillus rhamnosus* NCC2583 (CNCM I-2449), *Lactobacillus acidophilus* NCC2628 (CNCM I-2453) or *Enterococcus faecium* SF68 (NCIMB 10415). The corresponding dietary intake of the supplement for the pet is from about 10⁶-10¹² cfu/day, depending on the type of pet, e.g., a cat or a dog, and on the pet's

physical factors, such as body mass. The supplement is packaged such that it is removably attached to the can, together with feeding directions.

By way of example, and not limitation, experimental testing as described in detail below was conducted to demonstrate the effectiveness of the present invention.

5

In Vitro Testing 1

The inventors have conducted a number of experimental tests to demonstrate the beneficial effects of the present invention. In general, human colon cancer cell cultures were prepared and treated with varying amounts of chicory extracts over a
10 period of about 48 hours to evaluate the effects of chicory with respect to cyclooxygenase activity. The preparation and experimental testing procedures and results are discussed below in greater detail.

Preparation of Cell Culture

15 Colon cancer cell line HT-29 was obtained from the American Type Culture Collection and cultured in McCoy's 5A medium supplemented with 10% fetal bovine serum (FBS), 25mg/ml gentamicin. HT-29 cells were treated with a number of different chicory extracts made pursuant to an embodiment of the present invention as detailed below.

20

Preparation of Chicory Extracts

Four different chicory extracts, namely Extracts A-D, were prepared pursuant to an embodiment of the present invention. Initially, a 40 gram (g) and a 10g sample of chicory ground to powder form were each sieved at 0.5mm. The samples were then
25 processed to remove fats by mixing the samples with hexane for about thirty minutes at room temperature. 600 milliliters (ml) of hexane was added to the 40g chicory sieved sample, and 150ml was added to the 10g sieved sample. The hexane was evaporated under vacuum at about 50°C to form Extract A.

Extract B was prepared by first defatting 40g of ground chicory powder as
30 previously discussed. The defatted sample was hydrolyzed in 300ml of an acid, such as HCl, in a boiling water bath for about 20 minutes. After cooling and centrifugation (8000 rpm, 5 minutes, 10°C), the solution was extracted with 150ml of a solvent, such

as ethyl acetate, which is commercially available, such as from MERCK. The solvent is evaporated to dryness. After further drying on anhydrous sodium sulfate under vacuum at about 50°C, Extract B was formed.

Extracts C and D were prepared as follows. First, a 10g sample of ground chicory powder was defatted as previously discussed. The second part of the defatted powder is extracted with about 250ml of a solvent/water mix, such as a 1:1 volume ratio of MeOH and water in solution. The extraction is performed under stirring at room temperature (e.g., about 20°C to about 25°C) for about 30 minutes. After centrifugation, the solution is divided into two equal volumes. To the first volume part of the solution, the organic solvent is evaporated under vacuum at about 50°C. The remaining aqueous phase is freeze dried to form Extract C.

The second volume part of the solution is treated with about 2g of polyvinylpolypyrrolidone under stirring for about 30 minutes to trap polyphenols. The adsorbant material is removed by filtration, centrifugation or the like. The organic solvent is evaporated under vacuum at about 50°C. The remaining aqueous phase is freeze dried to form Extract D.

Measurement of PGE2 production

The effects of various chicory extracts, namely, Extracts A-C, on the biosynthesis of PGE2 were analysed in a human colon cell line HT-29. The biosynthesis of PGE2 provides an indication of the level of enzyme activity such as cyclooxygenase, as it is generally known that cyclooxygenase can act as a catalyst to produce PGE2 from, for example, Arachidonic acid. Thus, the effects of chicory extract on the enzyme activity of cyclooxygenase can be evaluated based on this experiment as described below.

Cells were grown for 48 hours in their media supplemented with 0.1% Bovine Serum Albumin (BSA) and 10 µM Arachidonic Acid. Chicory extracts were then added to these media at concentrations of 50, 100 and 200µg/ml for either 21 hours or for 15 hours. Another set of cell samples was prepared by adding chicory extract B to the HT-29 cells as discussed above followed by a co-incubation in the presence of 10ng/ml of Tumor Necrosis Factor alpha (TNF) for 6 hours. It is generally believed that the addition of TNF will stimulate inflammation.

The quantity of PGE2 in cell media was then determined with the PGE2 Monoclonal Enzyme Immunoassay Kit (Cayman Chemical) according to the manufacturer's instructions. Briefly, 25 or 50 µl of the medium, along with the serial diluted PGE2 standard samples, was mixed with appropriate amount of acetylcholineesterase-labeled tracer and PGE2 anti-serum and incubated at room temperature for 18 hours. After the wells were emptied and rinsed with wash buffer, 200 µl of Ellman's reagent that contained substrate for acetylcholine esterase was added. The enzyme reaction was carried out in a slow shaker at room temperature for 1 hour. Results were measured using a microplate reader at 415 nm and normalized to micrograms of protein.

The test results indicated that the chicory extract B, which was made with ethyl acetate as previously discussed, had the most pronounced effect on the inhibition of cyclooxygenase activity as evidenced by a decrease in the amount of PGE2 measured. In general, the decrease in cyclooxygenase activity was more pronounced with increasing amounts of chicory extract. Further, the test results indicated that the chicory extract B had a more pronounced effect on the inhibition of cyclooxygenase activity in the HT-29 cell line with TNF as compared to the HT-29 cell line without TNF. This suggests that the inhibition of cyclooxygenase activity may be more influenced by a specific inhibition of cyclooxygenase-2 as compared to cyclooxygenase-1. The results are presented in Table 1

Table 1. Effect of chicory extracts with ethylacetate (chicory extract B) on PGE-2 synthesis in HT-29 cells

Addition	PGE-2 levels (% of control) - TNF alpha	PGE-2 levels % of control + TNF-alpha*
Control (vehicle alone)	100	100
Chicory Extract B (100 mcg/ml)	95	80
Chicory extract B (200 mcg/ml)	33	0.7

* Stimulation of enzyme activity by TNF-alpha was 10-fold

In Vitro Testing 2

1. Inhibitory effects of α -CH₂- γ -butyrolactone on PGE₂ synthesis

The inventors have conducted a similar experimental test to demonstrate the anti-inflammatory effects of alpha-methylen-gamma-butyrolactone. In general, inhibition of PGE₂ synthesis by alpha-methylen-gamma-butyrolactone has been showed in HT29 cells stimulated by TNF-alpha. To this end, cells were cultured and passed in Mc Coy's 5A medium supplemented with arachidonic acid (10 microliter) and bovine serum albumin (0.01%). Cells were treated by alpha-methylen-gamma-butyrolactone (dissolved in methanol) at the following doses: 15, 30, 60 microM or by solvent alone during 21 h including or not stimulation with TNF-alpha (10 ng/ml) for 6 h. PGE₂ analysis was performed using an Elisa test on a medium sample.

	pg PGE ₂ /ml of medium - TNF- α	% of control	pg PGE ₂ /ml of medium + TNF- α	% of control
Méthanol control	2594	100	18941	730
α -CH ₂ - γ -butyrolactone 15 μ M	2814	108	13286	512
α -CH ₂ - γ -butyrolactone 30 μ M	1970	76	9349	360
α -CH ₂ - γ -butyrolactone 60 μ M	1144	14	1310	50

Table 2: PGE₂ concentration in pg/ml of medium in HT 29 cells treated with α -CH₂- γ -butyrolactone with and without TNF- α .

2. Inhibitory effects of α -CH₂- γ -butyrolactone on COX-2 expression

Western blot analysis: cells lysate were prepared by treating HT 29 cells (treated as above for PGE-2 determinations, *i.e.* in presence or absence of TNF-alpha and with or without α -CH₂- γ -butyrolactone) with lysis buffer (150 mM NaCl, 10mM Tris HCl pH 8, 1% Tween 20, EDTA pH 8 1mM, proteases inhibitors, PEFA, (Merck), DETC (Aldrich)). Lysates were sonicated for 5 s, and centrifugated at 10000g for 5 min. Proteins concentration were estimated by the Bradford method which was standardized using bovine serum albumine.

Whole cell extracts (25 μ g) were boiled in Laemmli sample buffer and resolved by SDS-PAGE on 10% gel using the discontinuous polyacrylamide gel system. Non specific binding sites were blocked by incubating the membrane in 5% dried milk phosphate buffered saline solution containing 0.1% of tween-20 overnight at 4°C.

Blots were hybridized in a 1:1000 dilution of a goat polyclonal anti COX-2 and also COX-1 antibody (C-20, Santa Cruz Biotechnology) in 5% milk PBS for 1h at room temperature followed by 1h of washing in 1% milk PBS. Subsequently, blots were probed with a secondary donkey anti-goat antibody horseradish peroxidase conjugated.

5 After washing for 1h, the complex was detected using ECL Western blotting reagents (Amersham)

The results are shown in Figure 1.

3. Specific inhibition of COX-2 activity by α -CH₂- γ -butyrolactone

10 The Stressgen StressXpressTM cyclooxygenases activity Kit provides a method to measure specifically cyclooxygenases COX-1 and COX-2 in a variety of biological fluids. The kit uses a specific chemiluminescent substrate (aromatic hydrocarbon molecule) to detect the peroxidative activity of COX enzymes. After inhibition by specific compounds (α -CH₂- γ -butyrolactone and NS- 938, a specific COX-2 inhibitor
15 from Cayman Chemical Company, both dissolved in methanol) the direct residual activity of cyclooxygenase is measured by addition of the chemiluminescent substrate and arachidonic acid (50 μ M). Light emission begins immediately and chemiluminescent signal (Relative Luminescence Units – RLU- is measured after 30 minutes (luminometer Tecan). The amount of light emitted is directly proportional to
20 the COX activity.

In this test, α -CH₂- γ -butyrolactone was found to inhibit specifically and with high potency COX-2 activity as did the reference compound NS-398. The results are presented in Table 3.

	COX-1 activity (RLU)	% of control	COX-2 activity (RLU)	% of control
Vehicle alone (methanol)	4115	100	26450	100
α-CH₂-γ-butyrolactone (40 μM)	4807	117	12823	49
NS-398 (1mM)	4063	99	1794	7
